Softmax exercise

Complete and hand in this completed worksheet (including its outputs and any supporting code outside of the worksheet) with your assignment submission.

In this exercise, you will:

- implement a fully-vectorized **loss function** for the Softmax classifier
- implement the fully-vectorized expression for its **analytic gradient**
- **check your implementation** with numerical gradient
- use a validation set to **tune the learning rate and regularization** strength
- **optimize** the loss function with **SGD**
- **visualize** the final learned weights

Acknowledgement: This exercise is adapted from Stanford CS231n.

Regression as classifier

The most simple and straightforward approach to learn a classifier is to map the input data (raw image values) to class label (one-hot vector). The loss function is defined as following:

$$L = \frac{1}{n} \| XW - y \|_F^2 (1)$$

Where:

- $W \in R^{(d+1) \times C}$: Classifier weight
- $X \in R^{n \times (d+1)}$: Dataset
- $y \in R^{n \times C}$: Class label (one-hot vector)

Optimization

Given the loss function (1), the next problem is how to solve the weight W. We now discuss 2 approaches:

- Random search
- Closed-form solution

Random search

```
bestloss = float('inf')
for num in range(100):
    W = np.random.randn(3073, 10) * 0.0001
    loss = np.linalg.norm(X_dev.dot(W) - y_dev_oh)
    if (loss < bestloss):
        bestloss = loss
        bestW = W
    print('in attempt %d the loss was %f, best %f' % (num, loss,
bestloss))
```

```
in attempt 0 the loss was 31.646948, best 31.646948
in attempt 1 the loss was 34.008923, best 31.646948

in attempt 97 the loss was 33.581988, best 29.729416
in attempt 98 the loss was 33.696833, best 29.729416
in attempt 99 the loss was 34.947318, best 29.729416
```

```
# How bestW perform:
print('Accuracy on train set: ', np.sum(np.argmin(np.abs(1 -
X_dev.dot(W)), axis=1) ==
y_dev).astype(np.float32)/y_dev.shape[0]*100)
print('Accuracy on test set: ', np.sum(np.argmin(np.abs(1 -
X_test.dot(W)), axis=1) ==
y_test).astype(np.float32)/y_test.shape[0]*100)
```

```
Accuracy on train set:  8.4
Accuracy on test set:  9.0
```

You can clearly see that the performance is very low, almost at the random level.

Closed-form solution

The closed-form solution is achieved by:

$$\frac{\partial L}{\partial W}=\frac{2}{n}X^T(XW-y)=0$$

$$\Leftrightarrow W^{\iota}=\left(X^T X\right)^{-1}X^T y$$

```
##############################################################
##########
# TODO:
#
# Implement the closed-form solution of the weight W.
#
##############################################################
##########
W =
np.linalg.inv(X_train.T.dot(X_train)).dot(X_train.T.dot(y_train_oh))
##############################################################
##########
#                                END OF YOUR CODE
#
##############################################################
##########
```

```
# Check accuracy:
print('Train set accuracy: ', np.sum(np.argmin(np.abs(1 -
X_train.dot(W)), axis=1) ==
y_train).astype(np.float32)/y_train.shape[0]*100)
print('Test set accuracy: ', np.sum(np.argmin(np.abs(1 -
X_test.dot(W)), axis=1) ==
y_test).astype(np.float32)/y_test.shape[0]*100)
```

```
Train set accuracy:  51.163265306122454
Test set accuracy:  36.199999999999996
```

Now, you can see that the performance is much better.

Regularization

A simple way to improve performance is to include the L2-regularization penalty.

$$L=\frac{1}{n}\left\| XW-y \right\|_F^2+\lambda \left\| W \right\|_F^2 (2)$$

The closed-form solution now is:

$$\Leftrightarrow W^{¿}=\left(X^T X+\lambda n I\right)^{-1} X^T y$$

```
# try several values of lambda to see how it helps:
lambdas = [0.01, 0.1, 1, 10, 100, 1000, 10000, 100000]
train_acc = np.zeros((len(lambdas)))
test_acc = np.zeros((len(lambdas)))
for i in range(len(lambdas)):
    l = lambdas[i]
    n,d = X_train.shape[0], X_train.shape[1]

################################################################################
##########
    # TODO:
#
    # Implement the closed-form solution of the weight W with
regularization.      #

################################################################################
##########
    W = X_train.T.dot(X_train)
    W = np.linalg.inv(W + (l * n * np.eye(W.shape[0])))
    W = W.dot(X_train.T.dot(y_train_oh))

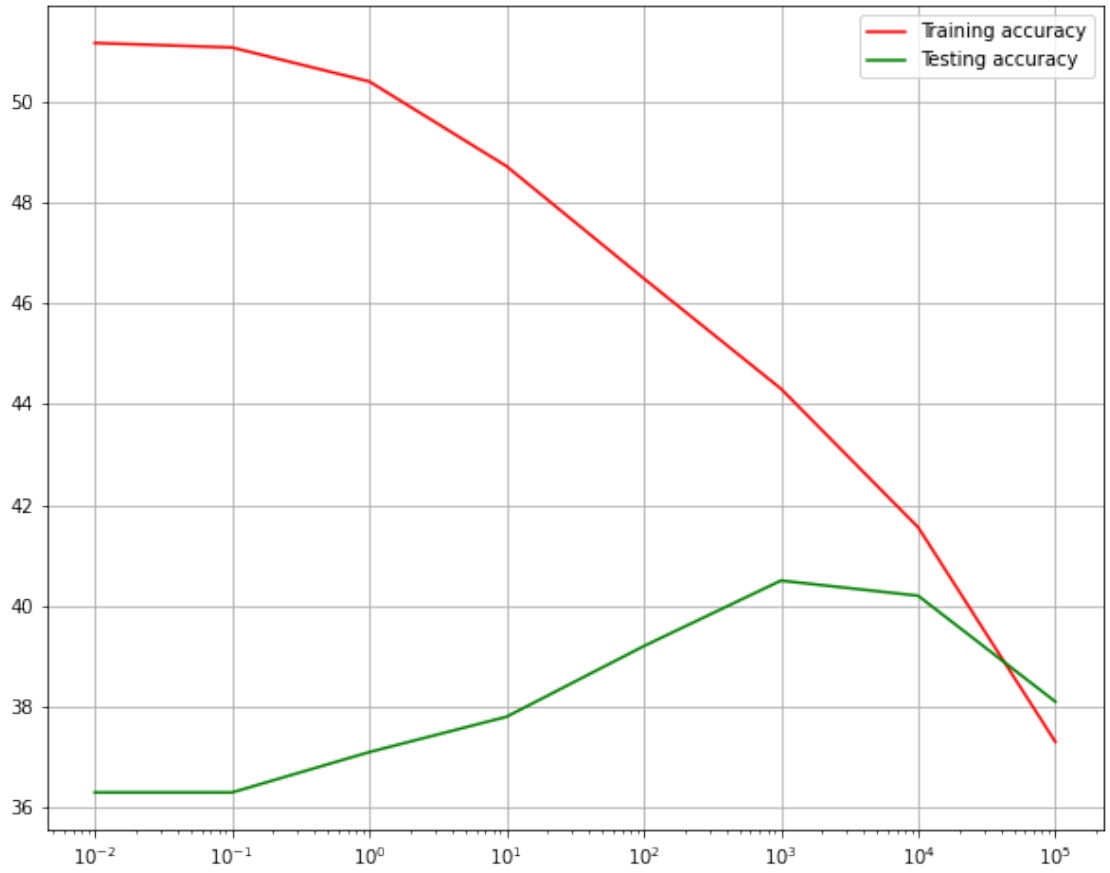
################################################################################
##########
    #                                END OF YOUR CODE
#

################################################################################
```

```
##########
    train_acc[i] = np.sum(np.argmin(np.abs(1 - X_train.dot(W)),
axis=1) == y_train).astype(np.float32)/y_train.shape[0]*100
    test_acc[i]  = np.sum(np.argmin(np.abs(1 - X_test.dot(W)), axis=1)
== y_test).astype(np.float32)/y_test.shape[0]*100

plt.semilogx(lambdas, train_acc, 'r', label="Training accuracy")
plt.semilogx(lambdas, test_acc, 'g', label="Testing accuracy")

plt.legend()
plt.grid(True)
plt.show()
```



Question: Try to explain why the performances on the training and test set have such behaviors as we change the value of λ.

Your answer: The regularization parameter compensates for overfitting in the training examples by introducing a penalty in the loss function. Therefore as increases there is an decrease in its training accuracy while as we move towards an optimal , the test accuracy increases to a certain point. Howver after that point, the penalty is too high when updating the weights causing a fall in accuracy in the test examples as well.

Softmax Classifier

The predicted probability for the j-th class given a sample vector x and a weight W is:

$$P(y=j \mid x)=\frac{e^{-xw_j}}{\sum_{c=1}^{C} e^{-xw_c}}$$

softmax

Your code for this section will all be written inside **classifiers/softmax.py**.

```
# First implement the naive softmax loss function with nested loops.
# Open the file classifiers/softmax.py and implement the
# softmax_loss_naive function.

from classifiers.softmax import softmax_loss_naive
import time

# Generate a random softmax weight matrix and use it to compute the
loss.
W = np.random.randn(3073, 10) * 0.0001
loss, grad = softmax_loss_naive(W, X_dev, y_dev, 0.0)

# As a rough sanity check, our loss should be something close to -
log(0.1).
print('loss: %f' % loss)
print('sanity check: %f' % (-np.log(0.1)))
```

```
loss: 2.350621
sanity check: 2.302585
```

Question: Why do we expect our loss to be close to -log(0.1)? Explain briefly.**

Your answer: There are 10 classes and the probabilty for a class to be the ground-truth class would be 0.1. Hence, the loss for random searching should be close to -log(0.1)

Optimization

Random search

```
bestloss = float('inf')
for num in range(100):
    W = np.random.randn(3073, 10) * 0.0001
    loss, _ = softmax_loss_naive(W, X_dev, y_dev, 0.0)
    if (loss < bestloss):
        bestloss = loss
        bestW = W
    print('in attempt %d the loss was %f, best %f' % (num, loss,
bestloss))
```

```
in attempt 0 the loss was 2.346179, best 2.346179

```
# How bestW perform on trainset
scores = X_train.dot(bestW)
y_pred = np.argmax(scores, axis=1)
print('Accuracy on train set %f' % np.mean(y_pred == y_train))

# evaluate performance of test set
scores = X_test.dot(bestW)
y_pred = np.argmax(scores, axis=1)
print('Accuracy on test set %f' % np.mean(y_pred == y_test))
```

```
Accuracy on train set 0.159245
Accuracy on test set 0.171000
```

Compare the performance when using random search with *regression classifier* and *softmax classifier*. You can see how much useful the softmax classifier is.

Stochastic Gradient descent

Even though it is possible to achieve closed-form solution with softmax classifier, it would be more complicated. In fact, we could achieve very good results with gradient descent approach. Additionally, in case of very large dataset, it is impossible to load the whole dataset into the memory. Gradient descent can help to optimize the loss function in batch.

$$W^{t+1} = W^t - \alpha \frac{\partial L\left(x; W^t\right)}{\partial W^t}$$

Where α is the learning rate, L is a loss function, and x is a batch of training dataset.

```
# Complete the implementation of softmax_loss_naive and implement a
(naive)
# version of the gradient that uses nested loops.
loss, grad = softmax_loss_naive(W, X_dev, y_dev, 0.0)

# Use numeric gradient checking as a debugging tool.
# The numeric gradient should be close to the analytic gradient.
from gradient_check import grad_check_sparse
f = lambda w: softmax_loss_naive(w, X_dev, y_dev, 0.0)[0]
grad_numerical = grad_check_sparse(f, W, grad, 10)

# gradient check with regularization
loss, grad = softmax_loss_naive(W, X_dev, y_dev, 1e2)
f = lambda w: softmax_loss_naive(w, X_dev, y_dev, 1e2)[0]
grad_numerical = grad_check_sparse(f, W, grad, 10)
